DT Scrum cycle Exercise

Phillip Llewellyn

7/19/2021

Decision Tree Scrum Cycle 7

Step 1

- Load data and get summaries

```
data <-read.csv("BankLoan Dataset 2021 - Clean .csv")  #HR.csv
#str(data)
data$lead <- as.factor(data$lead)
data$won <- as.factor(data$won)
summary(data)
```

```
##       X.1                X               RefNum             agerange

##
```

```r
#str(data)
```

Step 2

- Split data into training and testing data

```r
# separate the data for an equal split
data_lead_1 = data[data$lead == 1,]
data_lead_0 = data[data$lead == 0,]

#randomize the sampling
set.seed(15)
newDataset_lead_1 <-sample.split(Y=data_lead_1$lead, SplitRatio = 0.30)
newDataset_lead_0 <-sample.split(Y=data_lead_0$lead, SplitRatio = 0.65)

trainData <-rbind(data_lead_1[newDataset_lead_1,], data_lead_0[newDataset_lead_0,])
testData <- rbind(data_lead_1[!newDataset_lead_1,][1:130,], data_lead_0[!newDataset_lead_0,])

summary(trainData$lead)
```

```
##   0   1
## 227 231
```

```r
summary(testData$lead)
```

```
##   0   1
## 123 130
```

Step 3

- Fit a Decision Tree using training data

```r
# The . specifies all other columns ( Class ~ . )
DTmodel <- rpart(lead ~ education + age + job + marital + deposit + balance + loan + housing, method="cl
```

- Target Variable = Class,

- Input Vaiables = All,

- split =gini or information gain

- control = rpart.control for prepruning DT minsplit- min records at node for split to occur, maxdepth - depth of the DT

- Fitting the model

```r
rpart.plot(DTmodel, type=3, extra = 2, fallen.leaves = F, cex = 0.8)
```

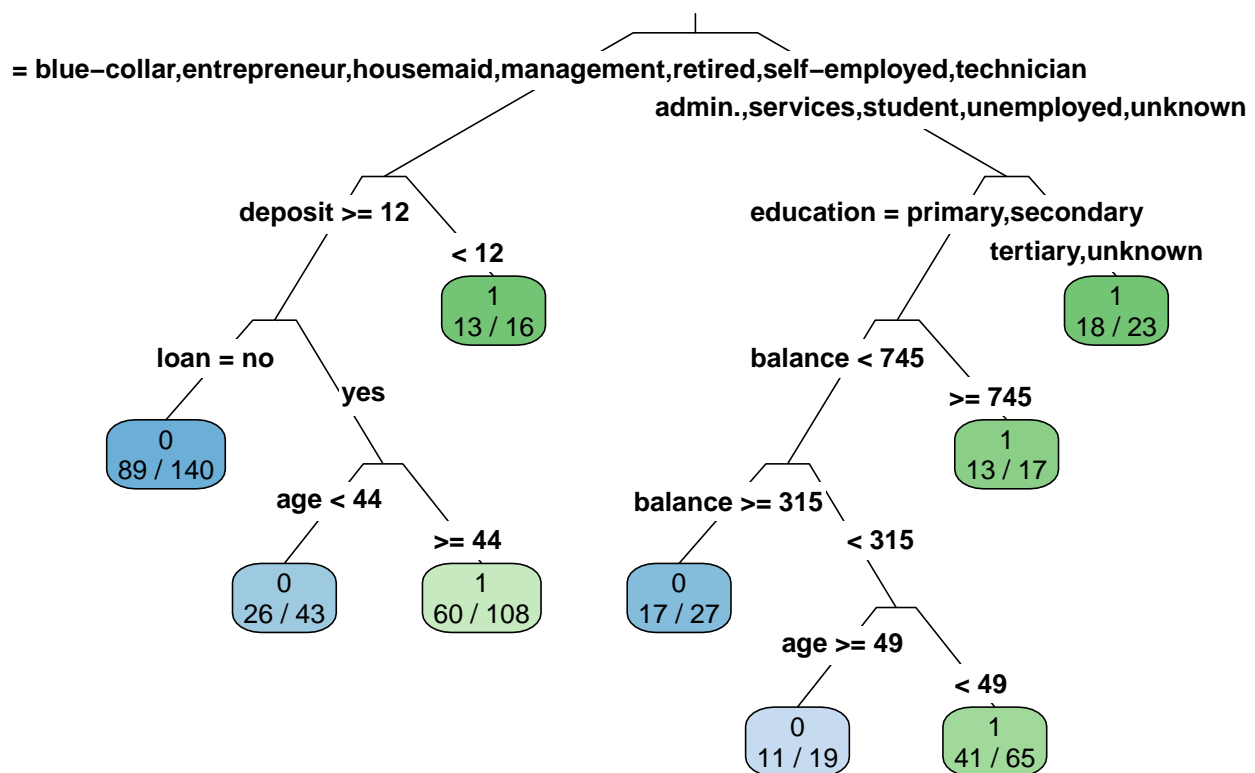

```r
#try extra with 2,8,4, 101
```

- Print out the information

```
#(DTmodel) # detailed summary of splits
DTmodel #prints the rules
```

```
## n= 458
##
## node), split, n, loss, yval, (yprob)
##       * denotes terminal node
##
##  1) root 458 227 1 (0.4956332 0.5043668)
##    2) job=blue-collar,entrepreneur,housemaid,management,retired,self-employed,technician 307 141 0 (0
##      4) deposit>=11.635 291 128 0 (0.5601375 0.4398625)
##        8) loan=no 140  51 0 (0.6357143 0.3642857) *
##        9) loan=yes 151  74 1 (0.4900662 0.5099338)
##         18) age< 43.5 43  17 0 (0.6046512 0.3953488) *
##         19) age>=43.5 108  48 1 (0.4444444 0.5555556) *
##      5) deposit< 11.635 16   3 1 (0.1875000 0.8125000) *
##    3) job=admin.,services,student,unemployed,unknown 151  61 1 (0.4039735 0.5960265)
##      6) education=primary,secondary 128  56 1 (0.4375000 0.5625000)
##       12) balance< 745 111  52 1 (0.4684685 0.5315315)
##         24) balance>=314.5 27  10 0 (0.6296296 0.3703704) *
##         25) balance< 314.5 84  35 1 (0.4166667 0.5833333)
##           50) age>=48.5 19   8 0 (0.5789474 0.4210526) *
##           51) age< 48.5 65  24 1 (0.3692308 0.6307692) *
##       13) balance>=745 17   4 1 (0.2352941 0.7647059) *
##      7) education=tertiary,unknown 23   5 1 (0.2173913 0.7826087) *
```

- Run the second model

```
#DTmodel2 <- J48(as.factor(Class) ~., trainData, control = Weka_control(R = TRUE, M = round(NROW(trainD

#DTmodel2 <- J48(as.factor(left) ~., trainData, control = Weka_control(R = TRUE, M = 50))

#IGDT5model <- J48(as.factor(eReader_Adoption)~., trainData ,control = Weka_control(R = TRUE, M = round

#IGDT10model <- J48(as.factor(eReader_Adoption)~., trainData ,control = Weka_control(R = TRUE, M = roun
```

- Plot the model

```
#plot(DTmodel)
```

Step 4

- Use the fitted model to do predictions for the test data

```
predTest <- predict(DTmodel, testData, type="class")
probTest <- predict(DTmodel, testData, type="prob")

actualTest <- testData$lead
```

Step 5

- Create Confusion Matrix and compute the misclassification error

```
t1 <- table(predictions=predTest, actual = actualTest)
t1 # Confusion matrix
```

```
##            actual
## predictions  0  1
##           0 70 49
##           1 53 81
```

```
accuracy1 <- sum(diag(t1))/sum(t1) * 100
accuracy1
```

```
## [1] 59.68379
```

```
#calculatee sensitivity
sensitivity <- t1[2,2]/sum(t1[2,]) *100
sensitivity
```
```
## [1] 60.44776
```

```
#calculate specificity
specificity <- t1[1,1]/sum(t1[1,]) *100
specificity
```

```
## [1] 58.82353
```

- Visualization of probabilities

```
hist(probTest[,2], breaks = 100)
```
Histogram of probTest[, 2]

- ROC and Area Under the Curve

```
ROC <- roc(actualTest, probTest[,2])
```

```
## Setting levels: control = 0, case = 1
```

```
## Setting direction: controls < cases
```

```
plot(ROC, col="blue")
```

```
AUC <- auc(ROC)
AUC
```

```
## Area under the curve: 0.6061
```

- A new dataframe with Predicted Prob, Actual Value and Predicted Value

```
predicted_data <- data.frame(Probs = probTest, Actual_Value= actualTest ,Predicted_Value = predTest )
  #predicted_data$Probs.0 <- Class 0 Probability
  #predicted_data$Probs.1 <-  Class 1 Probability
predicted_data <- predicted_data[order(predicted_data$Probs.1, decreasing=TRUE),] # Sort on Probabiliti
predicted_data$Rank <- 1:nrow(predicted_data) # Add a new variable rank
```

- plot the graph

```
ggplot(data=predicted_data, aes(x=Rank, y=Probs.1)) +
  geom_point(aes(color = Actual_Value)) + xlab("Index") + ylab("Predicted Probability of getting Diabet
```
Step 6

- Use model to make predictions on newdata. Note we can specify the newData as data.frame with one or many records

```
#newData <- data.frame(Nbr_Preg = 4 , Glucose_test = 100, Triceps_SF=40,BP =95, S_insulin = 150, BMI= 3

#predProbability <-predict(DTmodel, newData, type='prob')
#predProbability

## Performnce measures -
#setseed(1), gini
# Simplicity = 15 leaves
# Accuracy = 0.734
# AUC = 0.7627

#setseed(1), information
# Simplicity = 10 leaves
# Accuracy = 0.71
# AUC = 0.7834
```

Step 7

- EXAMINING STABILITY - Creating Decile Plots for Class 1 or 0 Sort

```
#-----Create empty df-------
#decileDF<- data.frame(matrix(ncol=3,nrow = 0))
#colnames(decileDF)<- c("Decile","per_correct_preds","No_correct_Preds","cum_preds")
#-----Initialize varables
#num_of_deciles=10
#Obs_per_decile<-nrow(predicted_data)/num_of_deciles
#decile_count=1
#start=1
#stop=(start-1) + Obs_per_decile
#prev_cum_pred<-0
#x=0
#-----Loop through DF and create deciles
#while (x < nrow(predicted_data)) {
#   subset<-predicted_data[c(start:stop),]
#   correct_count<- ifelse(subset$Actual_Value==subset$Predicted_Value,1,0)
#   no_correct_Preds<-sum(correct_count,na.rm = TRUE)
#   per_correct_Preds<-(no_correct_Preds/Obs_per_decile)*100
#   cum_preds<-no_correct_Preds+prev_cum_pred
#   addRow<-data.frame("Decile"=decile_count,"per_correct_preds"=per_correct_Preds,"No_correct_Preds"=no
#   decileDF<-rbind(decileDF,addRow)
#   prev_cum_pred<-prev_cum_pred+no_correct_Preds
#   start<-stop+1
#   stop=(start-1) + Obs_per_decile
#   x<-x+Obs_per_decile
#   decile_count<-decile_count+1
#}
#------Stability plot (correct preds per decile)
#plot(decileDF$Decile,decileDF$per_correct_preds,type = "l",xlab = "Decile",ylab = "Percentage of corre
```
